ABSTRACT

Green tea used for year has a popular cancer preventive activity. Researchers have showed green tea inhibited growth of cancer in the animals. This research has been done with awareness of positives effect of green tea, which is approved by researchers and the importance of treatment of opened skin wound. This work has been done experimentally. There were 56 male mice in 7 different groups. Different dose of water and alcohol such as 50, 150 and 300 μ L were injected. After anaesthetizing the mice, skin wound was created on the back of the mice by a 6-mm punch. While the mice in control group were treated by normal saline, water and alcohol extract of green tea was injected around the wound on the back of each mouse. The dimensions of ulcers and the recovery percent of the wound in the 1st, 3rd, 5th, 7th, 10th, 13th and 15th day of study were measured. Furthermore, the needful time for recovery was evaluated. Some histological studies were done as well. Two Specimen of wounds were supplied at 4th, 7th and 15th day of the study. In this way, fibroblasts, inflammation, epitheleum and endothelial cell of blood vessels from the wounds were studied. The results show that there are no significant differences among control, water and alcohol groups in recovery processes ($p > 0.05$.) Evaluation of recovery processes showed there were significant differences among these groups on 7th day of study ($p < 0.01$). Evaluation of recovery processes showed there were significant differences among three injected doses of study ($p < 0.001$). The degree of differences in fibroblasts, inflammation and epithelium distortion in different days for 6 groups ($p < 0.05$) was meaningful. According to these findings, although both water and alcohol extracts of green tea speed up the wound healing, there isn't any difference between the uses of water or alcohol extracts.

Keywords: Green tea, Wound healing, Water and Alcohol extract, Race NMRI

Wound healing, or wound repair, is an intricate process in which the skin (or another organ-tissue) repairs itself after injury. The classic model of wound healing is divided into three or four sequential, yet overlapping phases: hemostasis (not considered a phase by some authors), inflammatory, proliferative and remodeling. Upon injury to the skin, a set of complex biochemical events takes place in a closely orchestrated cascade to repair the damage [1].

Green tea is made from *Camellia Sinensis* [2]. Leaves of this plant are processed with minimal oxidation. It is mainly used in Asia specifically in China [3-4]. There have been extensive researches on the effects of green tea and results have been surprisingly pleasing. Some of the major potential benefits of green tea include; anti-Cancer properties, increases in metabolic rate, anti-diabetes effect, enhancement of mental alertness, improvement of immune system, improvement of quality of life for HIV-infected

50 patients, cardioprotective effects [5-8]. In this study, 51 green tea extracts has been investigated for their effects 52 on the opened skin wound healing.

MATERIALS AND METHODS

54 In this experimental research, 56 male mice of 55 NMRI race with average weight of 25-35 grams were 56 studied. The mice were held in 7 cages in Professor 57 Torabi Nejad Research Center in Isfahan with light 58 cycle of 12 hours darkness and 12 hours light in $22 \pm$ 59 2°C . In this period, sufficient water and food were in 60 hand of animals and they were randomly classified to 61 control and experimental groups.

62 Green tea extract was prepared using Soxhlet 63 instrument. The green tea leaves were studied by 64 Isfahan University and were transferred into laboratory. 65 Then using electric mill, they were grinded to a powder. 66 Forty grams of green tea powder was placed into 67 filtration paper and were transmitted to a specific 68 container. In order to produce water extract, 400 69 milliliters of purified water was added and in order to 70 produce alcoholic extract, 400 milliliters of 85% 71 methanol was added. After producing the extract by 72 Soxhlet, it was dried and concentrated in rotary 73 evaporator and then in 48-hour incubation in 70°C 74 Bonna. In next stage, 2 g of each extract (alcoholic or 75 aqueous) was solved in 100 mL normal saline and 76 therefore, 2% aqueous or alcoholic extract was 77 achieved.

78 In order to make a wound in animal, first the mouse 79 became comatose with ether and then its back hair was 80 shaved. After immersing the skin with betiding, with 6- 81 millimeter punch and in accordance to surgery 82 principles, a 6-millimeter wound was developed. The 83 wound depth was full skin thickness and the surgery day 84 was named the day zero. After making the wound, in 85 order to prevent potential putrefaction, 0.2 mg penicillin 86 and 0.2 mg gentamicin were injected.

87 The mice were injected 2% aqueous or alcoholic 88 extract for 7 days, once a day and at 9 am. The amount 89 of 50, 150 or 300 mL of extract were injected in four 90 direction surrounding the wound. All injection were 91 performed by one person. After developing the wound, 92 the mice were classified into 7 groups each 8, as 93 follows:

94 **Group 1 (control):** the wound surface of this group 95 was treated by normal saline;

96 **Groups 2, 3 and 4:** the wound surface was treated 97 by 50, 150 and 300 mL of 2% aqueous extract 98 respectively;

99 **Group 5, 6 and 7:** the wound surface was treated 100 with 50, 150 and 300 mL of 2% alcoholic extract 101 respectively.

102 For macroscopic study, on days 1, 3, 5, 7, 10, 13 and 103 15, the length measurement method of wound and 104 imaging with digital camera was used for all groups. 105 The development of wounds was assessed and the 106 wound stages according to imaging digital camera and 107 size measurement were recorded.

108 For microscopic evaluation, sampling and tissue 109 study was carried out. On days 4, 7 and 15, the mice 110 were killed by smelling ether in air. Then, two samples 111 were taken from wound tissue and surrounding skin 112 which were placed inside 10% Formalin solution. The 113 tissue processing and molding was done by paraffin and 114 wax and the German microtome with firm blade of 115 Leitz to develop width cuts including skin, bed with the 116 thickness of 4 microns. The cuts were painted by 117 Haematoxylin and Eosin (H&E) coloring methods and 118 edematous cell, fibroblasts and sweating sections were 119 recognized through quality method. The wound 120 improving was determined through rating the pathology 121 parameters as follows:

122 **Rating 1:** The tissues with no repeating 123 epithelisation and fibrosis tissue but with the low 124 numbers of vessels and extreme edema.

Table 1. The microscopic study of aqueous and alcoholic extract of green tea on days 4, 7 and 15 based on the inflammation, fibrosis, epithelium and blood vessels.

Parameter	Days	Groups						
		Control	Aqueous extract			Alcoholic extract		
			50 μ L	150 μ L	300 μ L	50 μ L	150 μ L	300 μ L

Rating 2: The tissues with repeating epithelisation, treatment group on the days 1, 3, 5, 7, 10, 13, and 15 low quantity fibrotic tissue, low number of vessels and has been illustrated in Fig 1. There is a meaningful extreme edema difference between groups ($p < 0.001$).

Rating 3: The tissues with epithelisation and The microscopic results show that edema, fibroblast fibroblast in small limit and also low number of vessels and epithelium amount in mice received aqueous or low edema. alcoholic extract did not have a meaningful difference.

Rating 4: The tissues with no edema and the edema, fibroblast and epithelium amount were medium number of epithelisation and fibroblast significantly different in groups received aqueous or

Rating 5: The tissues with complete epithelisation, alcoholic extracts when compared with control group ($p < 0.001$). In contrast, the blood vascular amount were vessels and no edema. not significantly different in groups received aqueous or

All the data were analyzed using one-way ANOVA alcoholic extracts when compared with control group by SPSS statistical software. The p values < 0.05 were (Table 1).

considered significant.

RESULTS

The average wound diameter in control group was 4.42 \pm 1.66 mm, in the group which received the alcoholic extract of green tea was 3.81 \pm 1.74 mm, and in the group which received aqueous extract of green tea, it was 3.93 \pm 1.69 mm. No meaningful difference between 3 groups was observed (not significant). The average of wound diameter among control and

DISCUSSION

There are 150 reports from *in vitro* and *in vivo* studies in the effects of green tea on skin. The primary focuses of these studies are the chemical carcinogens or photo carcinogens in animals [9]. Generally, The polyphenols which are present in teas are categorized as catechins. Green tea leaves contain six primary catechin compounds: catechin, gallaogatechin, epicatechin, epigallocatechin, epicatechin gallate, as well as

apigallocatechin gallate (also referred to as EGCG). The other researchers showed that glycoproteins have different biological activities like polyphenols cause the infusion, contrast and anti-tumor, anti-edema, anti-virus, anti-ratification, anti-propagation in epidermis Keratinocytes [9]. Catkins are oldness, and lowering the blood sugar [7-10]. Chemical also from polyphenol group that have anti-oxidant and structure of these molecules is the polyphenol of green anti-ratification property and have role in prevention of tea which is the beginner of antioxidant theory [11]. bleeding and reducing thrombosis [9]. From seventh EGCG is the primary combination of green tea day on, is the propagation stage [17]. On seventh day, in polyphenolitic that has properties like antioxidant, anti-treatment group, the wound surface is reducing in tumor, and anti-mutagenic [9]. The biological and contrast with control group that this shows the epidemiological studies in the past 10 years show that reconstruction stage commencement [14] or in other EGCG can be the preventer of tumor growth in chest, word, the earlier start of revival phase of collagen lung, liver, sweetbread, stomach, pancreas, skin, cyst, synthesis take place in this stage and collagen groups and prostate [11]. EGCG is the preventer of secretion of with more diameter are constructed and the width link chymotrypsin, tumor necrosis factor alpha and glucose-242 between molecules also change [18]. The collagen yarn 6-phosphate dehydrogenase in liver [11-12]. 243 causes the wound after healing to look like the tissue

In this study, there is not a meaningful difference before wounding and prevents the white and ugly scar. between the alcoholic and aqueous extract of green tea. In addition, increasing blood and oxygen availability to in studied groups. This finding is important for two wound location takes place through widening the veins reasons. Firstly, using green tea extract doesn't have 247 [19]. Researches show that green tea reduces blood any relationship with aqueous or alcoholic treatment. 248 sugar, blood lipids, blood pressure, heart disease Secondly, in this study, the effect of aqueous and 249 reduction, heart bit and also vein widening [11,20]. This alcoholic variables is excluded. In the current study, on 250 influences on the practical capacity of fibroblasts, fourth day, as the edema stage indicator is considered as 251 synthesis increase in collagen fibers and increase in the wound treatment process [13], the excess of edema 252 wound insistence because of increase in collagen in treatment group is meaningfully less than of control 253 content and because fibroblasts are responsible for group ($p < 0.001$). This shows that the green tea makes 254 developing collagen. So we can conclude that green tea the edema stage of treatment process faster and 255 (polyphenol, catechin and EGCG) cause the propagation therefore the wounds heal faster. In addition, injecting 256 of fibroblasts and influence the practical capacity of the 2% extract of green tea into mice wound caused 257 fibroblasts and increase the synthesis of fibro Collagen meaningful increases in fibrous tissue and reduction in 258 [20]. The higher the injection dose (300 mL), the higher the edema in seventh day of study in comparison to the 259 the meaningful number of fibroblasts [9]. The research control group. This meaningful increase of treatment 260 of Madham *et al.* show that catechin polyphenol and group fibrous in considering their role in following 261 EGCG prevent the collagenase activity against issues are important and indicate the positive effect of 262 Collagens [18]. In fact, Catkin and EGCG prevent the green tea on distribution phase of wound treatment 263 action through linking with hydrogen and reaction with process. 264 hydrophobic with collagens prevent its activity and play

1. Fibroblasts are responsible for synthesis of the 265 a role in collagens registration [18]. Research of Young matrix components of primary outer cell of wound bed 266 *et al.* also shows the prevention of collagen destruction including fibronectin and proteoglycans that provide a 267 and collagenase activity through setting reactions of proper substrate for immigration and propagation of 268 cellular signal by EGCG [19]. 269 cells [14]. 269 The broad studies during past decades show that the

2. The fibroblasts then synthesize the collagens that 270 healing process of wound through general and localized develop tension power in wound substrate [15]. 271 different factors is under influence [19]. Many different

3. Miofibroblasts that are exclusive fibroblasts 272 Neuron and hormonal like cell and vein factors or participate in wound shrinkage through providing 273 motion and secretory activities influence the wound contraction force [14]. 274 location. In this relation, we can point out to study of

During granulation, fibronectin develops a proper 275 EGCG and the properties of antibacterial and antivirus substrate for immigration and growth of cells and 276 of green tea in order to fasten the healing of wound therefore links with miofibroblasts so that wound 277 [20]. EGCG causes the propagation, division, and contraction is developed influentially. In addition, this 278 motivation of natural cells growth and does this through fibronectin is a support for fibrilligenesis [16]. 279 cell division and anti apoptosis division. Also, it Regarding the above-mentioned results, it was indicated 280 increases the Keratinocytes survival and influences on that the green tea extract has improved the wound 281 the propagation and fixing of fibroblasts [20]. The treatment at seventh day that these influences are 282 preventing effect of green tea is related to its anti-observed in reduction of wound surface and increase of 283 oxidant power. Polyphenols and glycoprotein play the healing percent and also in reduction of required time 284 role of scavenger in special conditions and thus it for complete healing. Reduction in edema resulted in 285 implements its preventing effects on bacteria and virus speeding the wound stage. In 2004, Bayer and colleges 286 growth. In this regard, preventing effect of green tea show that polyphenols prevent the discharge of gamma-287 (Camellia Sinensis) and black tea on the bacteria growth 288 interferon and have anti edema, anti oldness and wound 288 has been shown [21]. It is possible that green tea

improve the healing speed of wound. It has been reported that antibiotic medicine speeds the healing of wound by infection control [21]. But in this study the amount of collagen synthesis will exceed the exterior symptoms of infections are not observed in reconstruction of it [29]. In other hand, vitamin C is control group. Therefore, it seems to be actions other required for construction of veins, immigration of that preventing the wound infection for green tea for macrophages and correct function of neutrophils [30]. fastening the wound improvement. Bayat *et al.* explain Some studies show that green tea is a rich resource of the ultrasound treatment effect and gel on healing the vitamin C and includes 18 amino acids including lysine wound section and they believe that wet wound is the and proline [9,12,20]. Lack of vitamin B₆ (pyridoxine) speeding factor of wound healing process. In current damages this phenomenal link process. Lack of vitamin study, the wounds were daily wetted by the alcoholic B₂ (riboflavin) disorders the wound healing process and aqueous extract.

The experimental studies on animals show that the enzyme reactions and are required for correct function localized usages of epidermal growth factors have an of blood cells and construction of antibodies [30]. The important influence on speed of epidermal healing in results have shown that green tea includes vitamins B₁, wounds with relative thickness and burnings. The usage B₂ and B₆ [9,12,20]. Therefore probably we can of this material on human wounds also has similar conclude that mentioned issue is one of the factors effects and its usefulness has been proved [22]. The speeding the healing process in treatment group.

epidermal healing is a complex phenomena from which It seems that one of the functions of green tea that the rest epidermal cells are propagated so there will be helps the healing of wound is the positive effect of another healthy epidermis. The molecular actions that polyphenols, Catechin, Glycoproteins, EGCG and set the natural epidermal healing are not completely vitamins. The increased speed of healing has many known, but it seems that the peptide growth factors that effects regarding the economic and hygiene. Higher the act through autocrin or paracrin mechanisms have speed of wound healing, the less the wound infection important role on them [23-25]. In 2003, Chung *et al.* and an increased speed in all the process of wound showed that the green tea extract (EGCG) cause the healing. In all of current study for the first time it was epidemic creationists survival in human. In 2003, shown that green tea extract can speed the wound Bollag *et al.* proposed cellular propagation and healing healing process of male mice NMRI skin.

of wound through polyphenols of green tea. Many numbers of growth factors are known including the epidermal growth (EGF). This factor is a polypeptide of 53 amino acids that DNA and protein is activated by the mRNA [25]. It has been shown that the peptide growth factors increase significant proliferation of cells in wounds with relative wounds and also increase traction influence on Mesenchyme cells [26]. In fact, the growth factors of exterior peptide will increase other production of growth factors like transforming growth factor which is revealed from platelets and macrophages, indirectly activates the healing and improving the wound [27]. Without considering the structure, immediate facing of cells during healing with growth factors of epidermal, increases the epithelial [28]. Kwon *et al.* stated that EGCG motivates the growth of human hair through proliferation and has Anti-apoptosis effects on DPCs cells [28]. The histology of wound showed that proliferation of cells increase that is probably because of chemical combination of green tea and epidermal growth factors.

In addition, role of vitamins on wound healing process and the relationship of green tea contents with them can be considered. Lack of vitamin C is important in delay of wound healing. In such patients, wound healing in fibroplasia stage is stopped. In this state, even when the number of fibroblasts is natural, they do not produce sufficient collagen. Vitamin C is required for ion link of (OH) with amino acid of proline and lysine and hydroxyl of them inside fibroblast cell. Without hydroxy-lysine, fibrils of collagens will not obtain width links. In extreme Scurvy, not only the new
