ABSTRACT

Green tea used for year has a popular cancer preventive activity. Researchers have showed green tea inhibited growth of cancer in the animals. This research has been done with awareness of positives effect of green tea, which is approved by researchers and the importance of treatment of opened skin wound. This work has been done experimentally. There were 56 male mice in 7 different groups. Different dose of water and alcohol such as 50, 150 and 300 µL were injected. After anaesthetizing the mice, skin wound was created on the back of the mice by a 6-mm punch. While the mice in control group were treated by normal saline, water and alcohol extract of green tea was injected around the wound on the back of each mouse. The dimensions of ulcers and the recovery percent of the wound in the 1st, 3rd, 5th, 7th, 10th, 13th and 15th day of study were measured. Furthermore, the needful time for recovery was evaluated. Some histological studies were done as well. Two Specimen of wounds were supplied at 4th, 7th and 15th day of the study. In this way, fibroblasts, inflammation, epithelium and endothelial cell of blood vessels from the wounds were studied. The results show that there are no significant differences among control, water and alcohol groups in recovery processes (p > 0.05). Evaluation of recovery processes showed there were significant differences among these groups on 7th day of study (p < 0.01). Evaluation of recovery processes showed there were significant differences among three injected doses of study (p < 0.001). The degree of differences in fibroblasts, inflammation and epithelium distortion in different days for 6 groups (p < 0.05) was meaningful. According to these findings, although both water and alcohol extracts of green tea speed up the wound healing, there isn’t any difference between the uses of water or alcohol extracts.

Keywords: Green tea, Wound healing, Water and Alcohol extract, Race NMRI

Green tea is made from Camellia Sinensis [2]. Leaves of this plant are processed with minimal oxidation. It is mainly used in Asia specifically in China [3-4]. There have been extensive researches on the effects of green tea and results have been surprisingly pleasing. Some of the major potential benefits of green tea include; anti-Cancer properties, increases in metabolic rate, anti-diabetes effect, enhancement of mental alertness, improvement of immune system, improvement of quality of life for HIV-infected
Moshrefjavadi et al.

In this experimental research, 56 male mice of NMRI race with average weight of 25-35 grams were studied. The mice were held in 7 cages in Professor Torabi Nejad Research Center in Isfahan with light cycle of 12 hours darkness and 12 hours light in 22°C. In this period, sufficient water and food were in hand of animals and they were randomly classified to control and experimental groups.

Green tea extract was prepared using Soxhlet instrument. The green tea leaves were studied by Isfahan University and were transferred into laboratory. Then using electric mill, they were grinded to a powder. Forty grams of green tea powder was placed into filtration paper and were transmitted to a specific container. In order to produce water extract, 400 milliliters of purified water was added and in order to produce alcoholic extract, 400 milliliters of 85% methanol was added. After producing the extract by Soxhlet, it was dried and concentrated in rotary evaporator and then in 48-hour incubation in 70°C Boxenmary. In next stage, 2 g of each extract (alcoholic or aqueous) was solved in 100 mL normal saline and therefore, 2% aqueous or alcoholic extract was achieved.

In order to make a wound in animal, first the mouse became comatose with ether and then its back hair was shaved. After immersing the skin with betiding, with 6-millimeter punch and in accordance to surgery principles, a 6-millimeter wound was developed. The wound depth was full skin thickness and the surgery day was named the day zero. After making the wound, in order to prevent potential putrefaction, 0.2 mg penicillin and 0.2 mg gentamicin were injected.

The mice were injected 2% aqueous or alcoholic extract for 7 days, once a day and at 9 am. The amount of 50, 150 or 300 mL of extract were injected in four direction surrounding the wound. All injection were performed by one person. After developing the wound, the mice were classified into 7 groups each 8, as follows:

**Group 1 (control):** the wound surface of this group was treated by normal saline;

**Groups 2, 3 and 4:** the wound surface was treated by 50, 150 and 300 mL of 2% aqueous extract respectively;

**Group 5, 6 and 7:** the wound surface was treated with 50, 150 and 300 mL of 2% alcoholic extract respectively.

For macroscopic study, on days 1, 3, 5, 7, 10, 13 and 15, the length measurement method of wound and imaging with digital camera was used for all groups. The development of wounds was assessed and the wound stages according to imaging digital camera and size measurement were recorded.

For microscopic evaluation, sampling and tissue study was carried out. On days 4, 7 and 15, the mice were killed by smelling ether in air. Then, two samples were taken from wound tissue and surrounding skin which were placed inside 10% Formalin solution. The tissue processing and molding was done by paraffin and wax and the German microtome with firm blade of LEItz to develop width cuts including skin, bed with the thickness of 4 microns. The cuts were painted by Haematoxylin and Eosin (H&E) coloring methods and edematous cell, fibroblasts and sweating sections were recognized through quality method. The wound improving was determined through rating the pathology parameters as follows:

**Rating 1:** The tissues with no repeating epithelisation and fibrosis tissue but with the low numbers of vessels and extreme edema.
Table 1. The microscopic study of aqueous and alcoholic extract of green tea on days 4, 7 and 15 based on the inflammation, fibrosis, epithelium and blood vessels.

**Discussion**

There are 150 reports from in vitro and in vivo studies. The average wound diameter in control group was found to be 1.66 mm, in the group which received the alcoholic extract of green tea was 3.81 ± 1.74 mm, and in the group which received aqueous extract of green tea was 3.93 ± 1.69 mm. No meaningful difference was found between groups. The primary catechins in green tea leaves contain six primary catechins, which are present in teas are categorized as epicatechin, gallatecatechin, epicatechin, as well as...
apigallocatechin gallate (also referred to as EGCG). Healing [11]. The other researchers showed that glicoproteins have different biological activities like: polyphenols cause the infusion, contrast and anti-tumor, anti-edema, anti-virus, anti-ratification, anti-oxidant propagation in epidermis Keratinocytes [9]. Catkins are oldness, and lowering the blood sugar [7-10]. Chemical results also from polyphenol group that have anti-oxidant and structure of these molecules is the polyphenol of green tea which is the beginner of antioxidant theory [11]. EGCG is the primary combination of green tea: day on, is the propagation stage [17]. On seventh day, in polyphenolic that has properties like antioxidant, anti-oxidant, treatment group, the wound surface is reducing in tumor, and anti-mutagenic [9]. The biological and contrast with control group that this shows the epidemiological studies in the past 10 years show that: reconstruction stage commencement [14] or in other EGCG can be the preventer of tumor growth in chest, word, the earlier start of revival phase of collagen lung, liver, sweetbread, stomach, pancreas, skin, cyst, synthesis take place in this stage and collagen groups and prostate [11]. EGCG is the preventer of secretion of with more diameter are constructed and the width link chymotrypsin, tumor necrosis factor alpha and glucose-6-phosphate dehydrogenase in liver [11-12]. The higher the injection dose (300 mL), the higher the edema stage indicator is considered as: synthesis increase in collagen fibers and increase in the wound treatment process [13], the excess of edema wound insistence because of increase in collagen in treatment group is meaningfully less that of control content and because fibroblasts are responsible for group (p < 0.001). This shows that the green tea makes developing collagen. So we can conclude that green tea the edema stage of treatment process faster and: (polyphenol, catechin and EGCG) cause the propagation therefore the wounds heal faster. In addition, injecting 56 of fibroblasts and influence the practical capacity of the 2% extract of green tea into mice wound caused: 57 fibroblasts and increase the synthesis of fibro Collagen meaningful increases in fibrous tissue and reduction in DW [20]. The higher the injection dose (300 mL), the higher the edema in seventh day of study in comparison to these the meaningful number of fibroblasts [9]. The research control group. This meaningful increase of treatment end. Of Madham et al. show that catechin polyphenol and group fibrous in considering their role in following: EGCG prevent the collagenase activity against issues are important and indicate the positive effect of Collagens [18]. In fact, Catkin and EGCG prevent the green tea on distribution phase of wound treatment action through linking with hydrogen and reaction with process. Hydrophilic with collagens prevent its activity and play 1. Fibroblasts are responsible for synthesis of the role in collagens registration [18]. Research of Young matrix components of primary outer cell of wound bed: also shows the prevention of collagen destruction including fibronectin and proteoglycans that provide a cellular signal by EGCG [19]. The broad studies during past decades show that the 205 fibroblasts then synthesize the collagens that healing process of wound through general and localized develop tension power in wound substrate [15]. Many different 210 3. Miofibroblasts that are exclusive fibroblasts: Neuron and hormonal like cell and vein factors or participate in wound shrinkage through providing motion and secretary activities influence the wound contraction force [14]. Location. In this relation, we can point out to study of During granulation, fibronectin develops a proper EGCG and the properties of antibacterial and antivirus substrate for immigration and growth of cells and: 222 growth. Polyphenols and glycoprotein play the healing percent and also in reduction of required time role of scavenger in special conditions and thus it for complete healing. Reduction in edema resulted in: implements its preventing effects on bacteria and virus speeding the wound stage. In 2004, Bayer and colleges growth. In this regard, preventing effect of green tea show that polyphenols prevent the discharge of gamma-irradiated Camellia Sinensis) and black tea on the bacteria growth interferon and have anti edema, anti oldness and wound has been shown [21]. It is possible that green tea
Green tea effects on wounds healing

ARTICLE IN PRESS

improve the healing speed of wound. It has been reported that antibiotic medicine speeds the healing of wounds will lose their integrity and will open, Because the wound by infection control [21]. But in this study the amount of collagen synthesis will exceed the exterior symptoms of infections are not observed in the reconstruction of it [29]. In other hand, vitamin C is required for construction of veins, immigration of that preventing the wound infection for green tea and macrophages and correct function of nutrofiles [30], fastening the wound improvement. Bayat et al. explain Some studies show that green tea is a rich resource of the ultrasound treatment effect and gel on healing the vitamin C and includes 18 amino acids including lysine wound section and they believe that wet wound is the 357 and proline [9,12,20]. Lack of vitamin B6 (pyridoxine) speeding factor of wound healing process. In current study, the wounds were daily wetted by the alcoholic 359 B2 (riboflavin) disorders the wound healing process and aqueous extract [29]. In other hand, B group vitamins are cofactors for

The experimental studies on animals show that the enzyme reactions and are required for core function localized usages of epidermal growth factors have an effect of blood cells and construction of antibodies [30]. The important influence on speed of epidermal healing results have shown that green tea includes vitamins B1, 364 wounds with relative thickness and burnings. The usage of B6 [9,12,20]. Therefore probably we can of this material on human wounds also has similar conclude that mentioned issue is one of the factors effects and its usefulness has been proved [22]. The speeding the healing process in treatment group.

epidermal healing is a complex phenomena from which667. It seems that one of the functions of green tea that the rest epidermal cells are propagated so there will helps the healing of wound is the positive effect of another healthy epidermis. The molecular actions that polyphenols, Catechin, Glycoproteins, EGCG and set the natural epidermal healing are not completely vitamins. The increased speed of healing has many known, but it seems that the peptide growth factors that effects regarding the economic and hygiene. Higher the 372 act through autocrine or paracrine mechanisms have 373 speed of wound healing, the less the wound infection important role on them [23-25]. In 2003, Chung et al. and an increased speed in all the process of wound 375 showed that the green tea extract (EGCG) cause the healing. In all of current study for the first time it was epidemic creationists survival in human. In 2003, it shown that green tea extract can speed the wound Throwley et al. proposed cellular propagation and healing the process of male mice NMRI skin.

of wound through polyphenols of green tea. Many numbers of growth factors are known including the epidermal growth (EGF). This factor is a polypeptide of 53 amino acids that DNA and protein is activated by the mRNA [25]. It has been shown that the peptide growth factors increase significant proliferation of cells in wounds with relative wounds and also increase traction [26]. In fact, the growth factors of epidermis will increase production of growth factors like transforming growth factor which is revealed from plackets and macrophages, indirectly activates the healing and improving the wound [27, 28]. Without considering the structure, immediate facing of cells during healing with growth factors of epidermal, increases the epithelial [28], Kwon et al. stated that EGCG motivates the growth of human hair through 395 proliferation and has Anti-apoptosis effects on DPCs [36]. The histology of wound showed that proliferation of cells increase that is probably because of chemical combination of green tea and epidermal growth factors.

In addition, role of vitamins on wound healing process and the relationship of green tea contents with them can be considered. Lack of vitamin C is important in delay of wound healing. In such patients, wound healing in fibroblasts stage is stopped. In this case, even when the number of fibroblasts is natural, they do not produce sufficient collagen. Vitamin C is required for ion link of (OH) with amino acid of proline and lysine and hydroxy-l-lysine, fibrils of collagen will not obtain width links. In extreme Scurry, not only the new
